The zener diode is a semiconductor device unique in its mode of operation and completely unreplaceable by any other electronic device. Because of its unusual properties it fills a long-standing need in electronic circuitry.

Zener diodes are widely used to regulate the voltage across a circuit. When connected in parallel with a variable voltage source so that it is reverse biased, a Zener diode conducts when the voltage reaches the diode's reverse breakdown voltage. From that point it keeps the voltage at that value.

A Zener Diode is constructed for operation in the reverse breakdown re-gion. The relation between I-V is almost linear in this case  $V_z = V_{z0} + I_z r_z$ , where  $r_z$  is the dynamic resistance of the zener at the operating point.  $V_{z0}$  is the voltage at which the straight-line approximation of the I-V characteristic

Zener diodes are semiconductor PN junction diodes with controlled reverse-bias properties, which make them extremely useful as voltage references. The V-I characteristics of an ideal zener diode is shown in Figure 1 – 1 (a) and a simple regulator circuit based on it in Figure 1-1 (b). Sign in to download full-size image Figure 1-1.

Zener Diode : It is the reverse-biased heavily-dopped silicon (or germanium) P-N Junction diode which is operated in the breakdown region where current is limited by both external resistance and power dissipation of the diode. Silicon is preferred to diode because of its higher temperature and current capability.
